Abstract

Genetic variability analysis provides a guideline for the assessment of relative breeding potential of the parents which could be utilized either to exploit heterosis in F_1 hybrids or the accumulation of fixable genes to evolve a variety. Present study focussed on the assessment of yield potential and variability study in 48 genotypes of tomato. Genotypes under study showed greater potential with respect to growth parameters. Observations on phenological parameters revealed higher number of flowers in wild types compared to cultivated genotypes. Early flowering and early harvest were exhibited by wild types in comparison with cultivated genotypes. Compared to local checks, most of *Solanum lycopersicum* genotypes showed similar yield while some have exhibited higher yield. Genotypic and phenotypic coefficients of variability were high for plant height, number of branches, number of leaves, number of flower clusters, total number of fruits, polar circumference of fruit, transverse circumference of fruit, fruit weight, yield per plant and estimated yield per hectare. Heritability was high for all the 18 investigated traits. Genetic advance as per cent of mean was found high for all the characters except for total harvest duration.

Keywords : Tomato, Genotypes, Evaluation, Variability studies

The cultivated tomato, *Solanumly copersicum* L., is one of the world's most consumed vegetables due to its status as a basic ingredient in a large variety of raw, cooked or processed foods. Tomato is grown worldwide both as a local use crop or as an export crop and is second most remunerable vegetable after potato (Ashwini and Nagaraju, 2022). According to FAO STAT (Anonymous, 2022), the world's top five greatest producers of tomato were China, India, United States, Turkey and Egypt.

Decades of breeding have resulted in a significant loss to the genetic diversity in the crop plants. Genetic variability analysis is fundamental for the assessment of relative breeding potential of the parents which could be utilized either to exploit heterosis in F_1 hybrids or the accumulation of fixable genes to evolve a new variety. Genetic variability forms the basis for any breeding programme that may be resistance breeding or breeding for high yield. Correlation between performance of a genotype and attributing characters give insight for the selection of superior ones. Systematic studies and evaluation of genotypes are of great importance for present and future improvement of a crop (Tejaswini *et al.*, 2022). Morphological characterization is the initial phase in the description and classification of genotype collections.

Wide genetic diversity of *Solanum* spp has been reported in India. Quantification of diversity is vital to identify trait specific genotypes within the available germplasm. Repository of genes can be exploited and employed in tomato improvement programme. Keeping the above facts in view, the present study intends to assess variability among genotypes of tomato collected from different parts of India for growth, yield and quality parameters.

MATERIAL AND METHODS

In present study, 48 genotypes of tomato belonging to four different species were evaluated at the Vegetable Block of Horticulture Department, UAS, GKVK, Bengaluru during 2022-23. Among them, one belonged to *Solanum peruvianum* and *Solanum pimpinellifolium* each, two belonged to *Solanum ceraciforme* an drest of the genotypes belonged to *S. lycopersicum*. Arka Rakshak and Arka Abhed were used as local checks for yield. Details of the genetic material used in the study are furnished in Table 1.

Seedlings were raised in nursery for 28 days before transplanting. Transplanting was done onto raised beds prepared in field with plastic mulching. Spacing of 90×60 cm was followed while planting in randomized complete block design (RCBD) with three replications. Observations were recorded for 18 parameters. Analysis was done for significance of variance, genotypic coefficient of variation (GCV), phenotypic coefficient of variation (PCV), heritability, genetic advanceand path analysis.

RESULTS AND DISCUSSION

Mean Performance of Genotypes for Growth Parameters

Mean performance of genotypes for growth parameters is presented in Table 2. All the 48 geno types used in the study belonged to indeterminate type. Plant height of the genotypes at last harvest varied from 417.50 cm (C-269) to 158.75 cm (S-186). Forty five out of 48 genotypes under study showed taller plant habit than the local check varieties. WIR-3957 (365 cm), WIR-13708 (375 cm) and EC-520074 (377.5 cm) were some of the taller genotypes with statistically on par heights. Among the genotypes used in the study, number of branches varied from 50 (D-218) to 11.5 (S-186). Thirty out of 48 genotypes showed on par results with either of the checks. EC-520074 (S. pimpinellifolium) produced highest number of leaves (625.45). S-25 with 75.65 leaves was designated as genotype with lowest number of leaves. WIR-3957, WIR-13708, C-269, C-224, C-132 and S-143 produced more than 400 leaves per plant.

Genotypes under study showed greater potential with respect to characters like plant height, number of branches and number of leaves as proven by the results of evaluation for growth parameters. Their performance over local checks like Arka Abhed and Arka Raksak made them useful participants in crop improvement programme. Tomato being highly selfpollinated crop makes it easy to employ these traits in hybrid production.

Mean Performance of Genotypes for Phenological Parameters

Phenological parameters are plant characters that are related to flowering behaviour. Observations on these traits is presented in Table 3. Among the genotypes used in the study, S-187 (157.5) produced highest number of flower clusters. S-217 with 150 flower clusters was statistically on par with highest value. Lowest number of flower clusters was produced by S-48 (11.75). EC-520074, S-141 and C-194 produced more than 100 flower clusters.WIR-13708 (*S. ceraciforme*) produced earliest flower with 31 days after transplanting. WIR-3957, C-269, C-224 and C-

CHANDAN GUNAGA *et al*.

56 also produced early flowering with statistically on par data with the lowest. Latest flowering was seen in M-188 (54.5 days). WIR-13708 (S. ceraciforme) exhibited least number of days for 50 per cent flowering. C-269, C-224, C-253, S-219 and C-56 were also statistically on par with WIR-13708 for least number of days for 50 per cent flowering. M-188 with 55 days produced delayed 50 per cent flowering.

Observations on phenological parameters of genotypes reported higher number of flowers in wild types compared to cultivated genotypes, which was contributed by the presence of a greater number of flower bearing branches in wild types. Compared to local checks, the S. lycopersicum genotypes produced a greater number of flower clusters, which can be considered as a beneficial trait. In case of early flowering, again the wild types showed earlier flowering than cultivated genotypes. Most of the S. lycopersicum genotypes used in the study showed later or on-par commence of flowering with local checks.

Mean Performance of Genotypes for Harvest **Parameters**

Harvest parameters include days to first harvest, total harvest duration, number of fruits per cluster and number of fruits per plant (Table 4). Days to first harvest is an indication of earliness of the genotype. Among the genotypes studied, S-160 produced harvestable fruits at the earliest with 50.3 days after transplanting. WIR-13708, C-269, C-162 and C-56 showed statistically on par data with least value. M-188 showed latest harvest with 75.40 days after transplanting. In the present study longest harvest duration was observed in WIR-3957 with 99.74 days. M-23 with 98.75 days was statistically on par with WIR-3957. Least harvest duration was observed in D-218 (66.37 days). A greater number of fruits per cluster was observed in C-269 with 8.30 fruits per cluster. D-218 (8 fruits/ cluster) showed statistically on par value with C-269.

* Significant at 5% probability level

WA

Lowest number of fruits per cluster (4.20) was observed in S-143 and M-188. Genotype EC-520074 (*S. pimpinellifolium*) with 745 fruits showed highest number of fruits per plant. Among *S. lycopersicum* genotypes, C-253 with 315 fruits/plant was the highest. S-217 produced lowest number of fruits per plant with 59.34 fruits.

Early harvest was exhibited by wild types in comparison with cultivated genotypes. This trait was contributed by early flowering. While using wild types in breeding programme, breeder can target for transfer of earliness as proven by current study. Except for few, most of the cultivated genotypes showed on par commence of harvest with local checks. In case of number of fruits per plant, wild types showed the highest value. Compared with local checks the cultivated genotypes showed similar number of fruits per plant.

Mean Performance of Genotypes for Yield Parameters

Yield parameters include fruit weight, yield per plant and estimated yield per hectare (Table 5). Average weight of the fruit in the present study ranged from

115.23 g to 0.50 g. Highest fruit weight was recorded in C-56. Further, S-190 and S-33 exhibited fruit weight of more than 100 g. Lowest fruit weight was observed in D-218. Lowest value was also statistically on par with C-269 and EC-520074. Among the investigated genotypes, highest yield per plant was recorded in C-224 (9.26 kg). Other genotypes *viz.*, S-60, S-190, M-188, S-191, S-33, C-137, C-56, C-89 and S-160 also showed higher yields of more than 7 kg per plant. Lowest yield was reported in C-269 with 0.33 kg. The highest yielding genotype per hectare was C-224 with the yield of 101.83 tons. This value was on par with C-56 (99.47 t). Lowest yield per hectare was recorded in C-269.

The wild types with smaller fruits recorded least yield due to lower fruit weight. But wild types showed higher number of fruits per plant contributed by higher number of flowers. Compared to local checks, most of *S. lycopersicum* genotypes showed similar yield per hectare while some have exhibited higher yield.

Mean Performance of Genotypes for Fruit Parameters

Present study focused on fruit parameters like polar fruit circumference, transverse fruit circumference, shape index, TSS and shelf life (Table 6). S-190 with 21.34 cm was regarded as the genotype with longest polar fruit circumference. This value was statistically on par with S-33 with 20.00 cm. Lowest polar fruit circumference was recorded in D-218 with 4.00 cm. S-33 with 20.90 cm had the highest transverse fruit circumference. This value was statistically on par with L-193, S-190 and S-60. Lowest transverse fruit circumference was recorded in D-218 with 4.00 cm. Among the genotypes used in the study, S-48 with 1.27 exhibited the highest value. 22 genotypes showed shape index value of more than 1. The genotype, S-217 with 0.67 was the lowest. Genotype EC-520074 with 7.50 ° brix had the highest TSS. Likewise, L-193, M-208, WIR-13708, WIR-13706 and C-269 recorded higher TSS of more than 6 ° brix. Genotype

NK4

with lowest TSS was C-253 with 3 ° brix. In the present study EC-520074 exhibited longest shelf life with 15 days. WIR-13706, C-59, S-187, S-129, M-23, S-25, S-191, S-186, S-189, S-190, S-48, C-21 and S-76 showed better storability with longer shelf life. Shortest shelf life was recorded in S-143 with 8 days.

In general, it has been proven that yield is ultimately and primarily governed by average fruit weight and total number of fruits. In the present study, the fruit yield per plant differed significantly among genotypes which might be attributed to varied plant height, number of flowers per cluster, number of fruits per plant and fruit weight. Significantly highest fruit yield per plant (9.26 kg) was recorded in C-224 compared to other genotypes. Highest yield of C-224 was mainly due to a greater number of fruits per plant as well as a greater number of flowers and fruits per cluster in addition to comparatively a greater number of branches and plant height. Deepa and Thakur (2008) also obtained highest yield of 1347g per plant in AI-9 of tomato. The results reported by Shivanand (2008) and Renuka *et al.* (2014) in tomato and cherry tomato, respectively showed that the highest yield was due to highest number of fruits per plant supporting the present findings.

Genotypic and Phenotypic Coefficient of Variation

As observed in the study (Table 7), high GCV and PCV estimates were observed for the traits *viz.*, plant height (20.66% and 21.61%), number of branches per plant (33.43% and 34.57%), number of leaves per plant (64.62% and 65.91%), number of flower clusters (54.30%, 56.45%), total number of fruits per plant (58.69%, 59.86%), polar circumference of fruit (26.78%, 27.31%), transverse circumference of fruit (24.78%, 25.28%), average fruit weight (53.45%, 54.52%), yield per plant (41.18%, 42.01%) and estimated yield per hectare (41.23%, 42.06%). Medium GCV and PCV were observed in days to first flowering (14.51%, 15.03%), days to 50 per cent

flowering (14.78%, 15.07%), days to first harvest (10.20%, 10.41%), number of fruits per cluster (17.04%, 17.38%), shape index (10.48%, 10.69%), TSS (17.97%, 18.33%) and shelf life (14.01%, 14.30%). Low GCV and PCV was observed in total harvest duration (9.55% and 9.74%). Such kind of variability was also observed by Islam *et al.* (2012). Similar works were also conducted by Patel *et al.* (2001), Muniappan *et al.* (2010), Ahmad *et al.* (2013) and Deshmukh *et al.* (2014).

The expression of characters was governed by genotypic effect as well as environmental effect. Phenotypic expression of characters such as plant height, number of branches, number of leaves was attributed to nature of genotype. Variation between genotypic and phenotypic expressions of characters was discussed to be governed by the effect of environment.

Heritability and Genetic Advance

High heritability as well as genetic advance were reported for plant height, number of branches, number of leaves, days to first flowering, days to 50 per cent flowering, number of flower clusters, days to first harvest, number of fruits per cluster, number of fruits per plant, polar fruit circumference, transverse fruit circumference, shape index, fruit weight, TSS, shelf life, yield per plant and estimated yield per hectare. Experimental findings of Negi et al. (2000) revealed that most of the traits showed high estimates of heritability (>70 per cent). High genetic advance coupled with high heritability was exhibited by number of fruits per plant, fruit yield per plant and average fruit weight suggesting predominance of additive gene action. Days to 50 per cent flowering and picking had high heritability and low genetic advance. Prasad et al. (2004) observed moderate genetic advance and heritability for plant height, days to first flowering and days to first fruit set. The heritability estimates were high (above 87 per cent) for all the characters according to the study of Singh and Kumar (2005). Similar results were also obtained by Golani et al. (2007).

Tomato is a highly self-pollinated crop. Due to homozygous condition, any new genotype that performs well for yield and yield attributing characters can be directly released as a variety. Present study revealed many such genotypes like C-224, S-160, C-89, C-56, S-60 and S-190 which showed higher yield than the local check Arka Abhed. High GCV and PCV recorded for most of the characters studied revealed the presence of variability among the population used in the study which is a desirable outcome to design crop improvement programmes. Recording of high heritability and genetic advance were also useful in view of using present material in future breeding programme. High heritability and genetic advance made sure that selection for these traits can be planned in progenies produced using present genotypes.
